## Memorandum

To: Rick Goncalves, P.E., TAC Chairman

CC: Dorothy Eisenbraun, P.E., AMEC
From: William P. Ruzzo, P.E.
Date: November 18, 2011, Revised December 2, 2011
Re: West Boat Ramp Parking Lot Improvements - Water Quality Analysis

Presented in this memorandum is an evaluation of water quality benefits associated with alternative plans to reduce water quality impacts from the West Boat Ramp Parking lot located in Cherry Creek State Park.

AMEC was retained by the Authority to prepare a PRF water quality management plan for the West Boat Ramp Parking Lot (Project). The management plan includes, among other tasks, identification and investigation of alternatives to reduce water quality impacts to Cherry Creek reservoir from storm runoff. AMEC has identified four alternative plans ${ }^{1}$ to address water quality impacts from the Project area and prepared conceptual level plans and a cost estimate for each alternative plan. Each of these alternative plans were then evaluated by the Authority for water quality benefits associated with reduction in total phosphorus (Tp), total suspended sediment (TSS), and oil/grease. The results of the analysis are presented herein.

AMEC presented the recommended plan to the Technical Advisory Committee (TAC) at the December 1, 2011 meeting. The TAC requested that the water quality analysis include the status quo or no-action alternative; therefore this memorandum was revised to include a discussion of this alternative.

## APPROACH

Water quality benefits for the Project were calculated based on reduction in annual pollutant loads that are discharged to the Reservoir, namely Tp, TSS, and oil/grease. The hydrologic basis for all alternatives is to capture runoff up to the storm inlet capacity (approximately the 5-year) and either divert runoff to a detention pond or

[^0]treat the runoff using a proprietary BMP prior to discharging into the Reservoir. To evaluate water quality benefits, calculations were made to determine:

1. Annual Tp and TSS loads from the Project area.
2. Estimate of the long-term performance in Tp and TSS for each alternative described below:
2.1. Alternative $1-\mathrm{A}:$ Water quality detention with pipe conveyance
2.2. Alternative 1-B: Water quality detention with pipe and swale conveyance
2.3. Alternative 2-A: Proprietary BMP - Hydrodynamic Separator
2.4. Alternative 2-B: Proprietary BMP - Filtration System
3. Calculation of annual Tp and TSS reduction load reduction for each alternative.
4. Comparison of the capital and annual costs per pound of Tp and TSS for each alternative.

Because quantification of oil/grease is not available, the ability of each alternative to control oil/grease was qualitatively evaluated relative to other alternatives investigated.

Calculations and data used to perform the analysis are attached to this memorandum.

## Annual Tp and TSS Loads.

Determination of annual loads was made using event mean concentrations (EMC) and estimate of mean annual storm runoff from the Project area. EMCs for Tp were obtained from the Authority's watershed model ${ }^{2}$, which were derived specifically for the Cherry Creek watershed. EMC's for TSS were obtained from Table 1-1 in Urban Drainage \& Flood Control District ( UDFCD $^{3}$ ) Volume 3 Manual.
Calculation of mean storm runoff volume procedures are also documented in the Authority's watershed model report. Annual Tp and TSS load calculations are provided on Sheet $1 / 2$ in the appendix.

## Performance Estimate.

The alternatives represent four different treatment technologies including extended detention basin (EDB), grassed swale, proprietary filter system, and proprietary hydrodynamic system. The primary source for performance of these BMPs can be found in the UDFCD Volume 3 Manual in Table 2-2.

As presented in Table 2-2, BMP performance (i.e.: effluent concentration) is dependent on influent concentration. Therefore, adjustments to the BMP performance (i.e.: effluent concentration) were necessary, since EMC used in this analysis differ from the data set provided in Table 2-2. The adjustment in performance was calculated as the ratio of Table 2-2 effluent to influent

[^1]concentration times the EMC used in the Authority's analysis. Calculations of these adjustments are provided in sheet $2 / 3$ of the appendix.

In addition to the performance adjustments, it was also necessary to make assumptions for the ability of the hydrodynamic separator to remove Tp and TSS, due to lack of available data. For the Authority's analysis, the hydrodynamic separator was assumed to remove $10 \%$ of the Tp and $75 \%$ of TSS, due to its ability to trap fine sediment.
For the proprietary filter system, the performance values listed in Table 2-2 for "media filters" were used to calculate BMP effluent concentrations.

Calculations of annual Tp and TSS load reductions for alternatives 1-A and 1-B are provided on Sheet 3/4 and calculations for alternatives 2-A and 2-B are provided on Sheet 4/-.

No-Action Alternative. The no-action alternative assumes that no improvements will be made to reduce the discharge of pollutants to Cherry Creek Reservoir. This means that phosphorus, sediment, and oil and grease would continue to drain into the reservoir during storm events.
Pollutants have a negative impact on reservoir water quality, therefore, beneficial uses (i.e.: swimming, boating, fishing, etc.) can be impaired which in turn has a negative impact on the economic value of the reservoir. Economic analysis of Cherry Creek Reservoir has estimated the present value may be over $\$ 1$ billion ${ }^{4}$. However, no attempt has been made to quantify or otherwise estimate the economic impact of the no-action alternative associated with park uses for recreation.

The financial impact of a no-action alternative is related, at least in part, to the cost to prevent or minimize the discharge of pollutants. The Authority evaluated 27 individual projects on its long term capital improvement program (CIP) list to determine cost per pound of phosphorus that is prevented from being discharged to the reservoir by construction of the project. The cost per pound ranges from $\$ 100$ to over $\$ 2,500$ per pound with an annual average around $\$ 1,100$. Data regarding cost of preventing sediment from being discharge to the reservoir is not available and no estimate was made for this water quality analysis.

## RESULTS

Presented in the following table is a summary of alternative costs, reduction in annual Tp and TSS loads, and a qualitative assessment of their ability to reduce oil and grease from being discharged to the Reservoir.

[^2]Summary of Water Quality Benefits for each Alternative

| Altern. | Description | Cost |  |  | Phosphorus Treatment |  | Sediment <br> Treatment |  | Oil and Grease |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Capital | O\&M | Annual |  |  |  |  |  |
|  |  | (usd) | (usd) | (usd) | (lbs) | \$/lb | (lbs) | \$/lb |  |
|  | No-Action | \$ | \$ - | \$ 1,100 | 2.6 | \$ 2,854 | 1,796 | --- |  |
| 1-A | EDB w/Pipe Diversion | \$ 209,880 | \$ 1,000 | \$ 12,245 | 1.4 | \$ 9,050 | 1,308 | \$ 9 | Poor to good w/baffle system at inlet |
| 1-B | EDB w/Pipe \& Swale Diversion | \$ 140,863 | \$ 1,500 | \$ 9,048 | 1.4 | \$ 6,680 | 1,635 | \$ 6 | Poor to good w/baffle system at inlet |
| 2-A | Proprietary Hydrodynamic Separator | \$ 180,327 | \$ 22,000 | \$ 31,663 | 0.3 | \$ 122,050 | 1,347 | \$ 24 | Good |
| 2-B | Proprietary Filter System | \$ 269,418 | \$ 27,000 | \$ 28,448 | 1.2 | \$ 24,370 | 1,469 | \$ 19 | Good to Very Good |

Note that for the "no-action" alternative, the average annual cost of phosphorus that is prevented from being discharged to the reservoir (i.e.: $\$ 1,100$ ) is believed to be a conservatively low value since it does not include economic impacts to recreational uses of the reservoir.

Based on this comparison, Alternate 1-B is the highest ranked alternative because:

1. It has the lowest annual cost
2. It has the lowest annual cost per pound of phosphorus and sediment removed.

Urban Storm Drainage Crieria Manual Volume 3, Table 1-2 \& 2-2

## EXTENDED DETENTION BASIN/WET POND

1. The existing boat storage pond will retain some runoff and infiltrate into the ground or evaporate Therefore, use "retention pond" EMC in Table 2-2 for influent and effluent
2. Use UDFCD Table 2-2 to estimate effluent (discharge) EMC, but adjust effluent EMC based on ratio of effluent/influent concentrations, similar to \% reduction

Table 2-2 EMC Values

| Total Phosphorus |  |  | Total Suspended Solids |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Influent | Effluent | Ratio | Influent | Effluent |  |
| (mg/l) | (mg/l) | (E/I) | (mg/l) | (mg/l) | (E/I) |
| 0.23 | 0.11 | 0.48 | 44.5 | 12.1 | 0.27 |

## GRASSED SWALE

1. Use UDFCD Table 2-2 to estimate effluent (discharge) EMC, but adjust effluent EMC based on ratio of effluent/influent concentrations, similar to \% reduction

Table 2-2 EMC Values

| Total Phosphorus |  |  | Total Suspended Solids |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Influent | Effluent | Ratio | Influent | Effluent | Ratio |
| (mg/l) | (mg/l) | (E/I)* | (mg/l) | (mg/l) | (E/I) |
| 0.22 | 0.23 | 1.0 | 54.5 | 18 | 0.33 |
|  | Assume no Total P reduction through grass swale |  |  |  |  |

## PROPRIETARY FILTER SYSTEM

1. Use UDFCD Table 2-2 to estimate effluent (discharge) EMC, but adjust effluent EMC based on ratio of effluent/influent concentrations, similar to \% reduction
2. Assume the "media filters" performance is similar to proprietary filter system

Table 2-2 EMC Values

| Total Phosphorus |  |  |  | Total Suspended Solids |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Influent | Effluent | Ratio | Influent | Effluent | Ratio |  |
| $(\mathrm{mg} / \mathrm{l})$ | $(\mathrm{mg} / \mathrm{l})$ | (E/l) | $(\mathrm{mg} / \mathrm{l})$ | $(\mathrm{mg} / \mathrm{l})$ | (E/l) |  |
| 0.2 | 0.11 | 0.55 | 44 | 8 | 0.18 |  |

PROPRIETARY HYDRODYNAMIC SEPARATOR

1. Use UDFCD Table 2-2 to estimate effluent (discharge) EMC, but adjust effluent EMC based on ratio of effluent/influent concentrations, similar to \% reduction
2. Assume that separator will reduce TP by $10 \%$ and TSS by $75 \%$

Table 2-2 EMC Values

| Total Phosphorus |  |  |  | Total Suspended Solids |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Influent | Effluent | Ratio | Influent | Effluent | Ratio |  |

[^3]:    Table Key
    NA $=$ Not available; studies containing 3 or more storms not available.
    $\mathbf{N C}=$ Not calculated because fewer than 3 BMP studies for this category
    Interquartile Range $=25$ th percentile to 75 th percentile values, calculated in Excel, which uses linear interpolation to calculate percentiles. For small sample sizes (particularly n $<5$ ),
    interquartile values may vary depending on statistical package used.
    **Permeable pavement data should be used with caution due to limited numbers of BMP studies and small numbers of storm events typically monitored at these sites. "Inflow" values are typically outflows monitored at a reference conventional paving site.
    Descriptive statistics calculated by weighting each BMP study equally. Each BMP study is represented by the median analyte value reported for all storms monitored at each BMP (i.e., "n" $=$ number of BMP studies, as opposed to number of storm events). Depending on the
    analysis objectives, researchers may also choose to use a storm-weighted analysis approach, a unit treatment process-based grouping of studies, or other screening based on design parameters and site-specific characteristics.
    
    
     Weighted" (all storms for all BMPs included in statistical calculations) appres. Values below detection limits replaced with $1 / 2$ of detection limit.
