PRELIMINARY REPORT

LIMNOCORRAL STUDY OF CHERRY CREEK RESERVOIR

INTRODUCTION

This is a preliminary report on the results of a study utilizing limnocorras to conduct specific scientific tests on the response of Cherry Creek Reservoir to the addition of alum and phosphorus. The work was conducted by Advanced Aquatic Technology Associates, Inc. (AATA), and involved several phases. First, limnocorras were constructed of special plastic sheeting material by Dr. Frank Vertucci. All limnocorras were 2 meters in diameter. Three were constructed to be installed at a depth of 20 feet, and three were constructed to be installed at a depth of 30 feet.

CONSTRUCTION AND INSTALLATION

The limnocorras were constructed of polyethylene plastic sewn into a cylinder 2 meters in diameter. Three limnocorras were 20 feet long, while another set was constructed in a 30 foot length. These occupied the shallow and deep sample sites in Cherry Creek Reservoir respectively. The limnocorras were designed with a pocket at the top edge of the corral which contained empty 1-gallon milk containers and served both as a float and as a small obstruction to waves overtopping into the corral. Three additional smaller pockets were sewn into the sides of the limnocorras to provide a containment for a semi-rigid length of PVC pipe. These pipe hoops served to maintain the circular shape of the limnocorral.

The limnocorras were installed near the outlet structure in Cherry Creek Reservoir using diver assistance on July 15, 1991. Initial lake conditions were recorded and treatments were administered after equilibration on July 16, 1991.

The limnocorras were anchored in water just shallower than their overall length. Divers were used to anchor the bottom of the corral in the reservoir sediment. A good seal between the

corral and the sediment was required for isolation of the treated water from the rest of the reservoir. The limnocorras were further secured in a radial manner to anchors located 15 to 20 feet from the corrals.

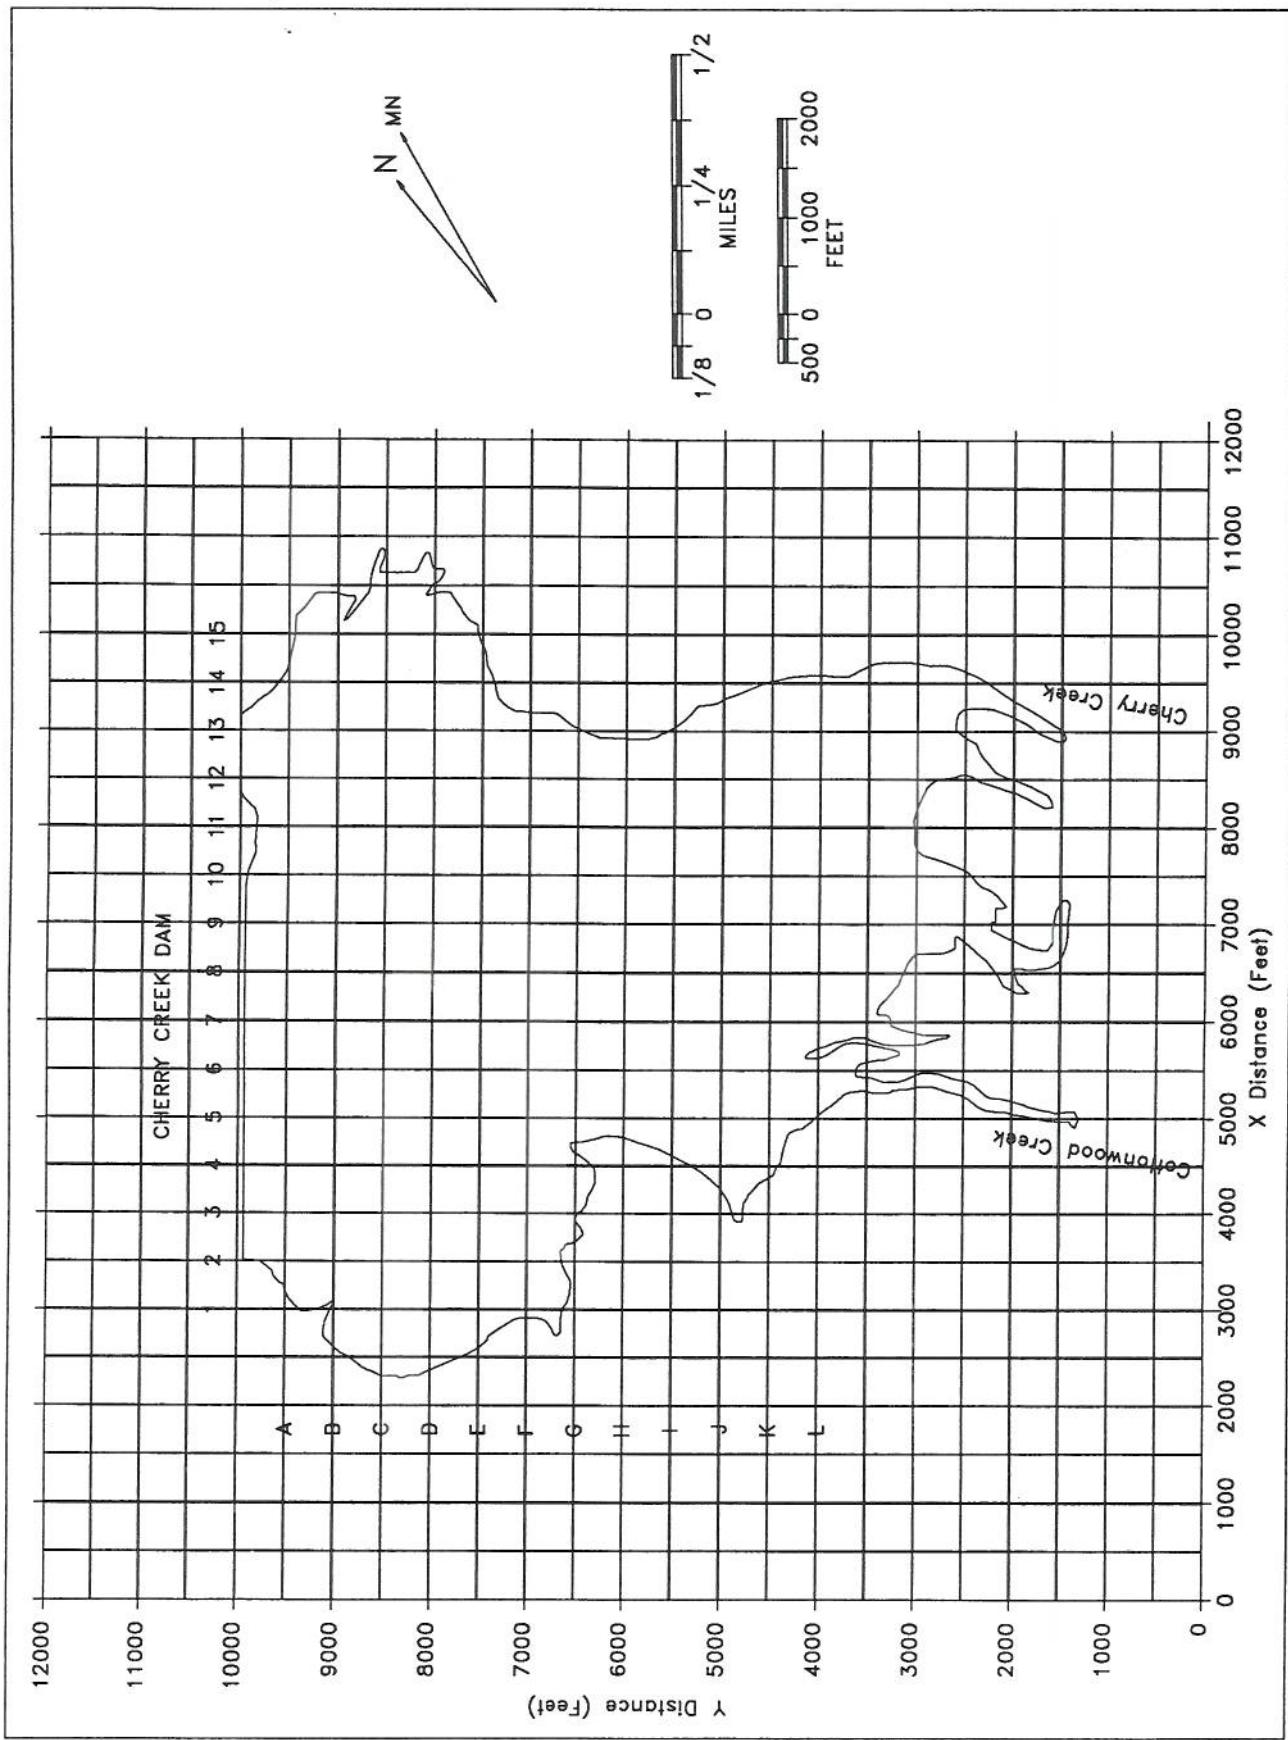

Sample sites were selected to be representative of the entire reservoir. A site corresponding to a water depth of about 18 feet was located near the C-14 grid point (Map 1). A second site was located near the B-13 grid point in approximately 25 feet of water. These sites were outside of the heavily used ski boat lanes, and were further marked with hazard buoys to prevent possible conflict with the boating activity.

In the limnocorral used to test the effect of phosphorus addition, the phosphorous concentration was elevated by $613\text{ }\mu\text{g-P/L}$, the same level as used in the 3.3X concentration of the limited nutrient study. This augmented phosphorous concentration was approximately 100 times the average annual measured phosphorous concentration.

The limnocorral used to test phosphorous removal contained an aluminum concentration of 20 mg/l. Aluminum sulfate and Sodium aluminate were added in a 1:1.6 ratio as suggested by Dominie (1980). The inclusion of the Sodium aluminate tends to buffer the pH of the system, preventing the significant drop in pH often seen with pure precipitation of phosphorous using only Aluminum sulfate.

SAMPLING AND FIELD MEASUREMENTS

Field measurements were made of dissolved oxygen and temperature profiles, pH, alkalinity, conductivity, and Secchi disc visibility on Day 3, 7, 14, and 21. Some limited information was generated for the 30 foot limnocorras at Day 28. A strong thunderstorm disturbed the 20 foot limnocorras on Day 19, as waves of approximately 4 feet ripped them from their moorings. Data collected beyond Day 19 are not deemed to be representative for the 20 foot limnocorras. Comparison with data in the 30 foot sets confirms that a nearly total evacuation of the test water occurred due to the storm. Water samples from the surface, mid-depth, and bottom were collected with an inert Beta bottle, cooled, and returned to the AATA lab where they were prepared for analysis of nutrients, chlorophyll, and other water chemistry. Samples

Map 1

were shipped using overnight express to Inter-Mountain Labs (IML), Sheridan, Wyoming for analysis.

ANALYSIS

Analysis of the water samples was conducted according to standard EPA protocols (see attached lab sheets for listings). Method comparisons were conducted, along with normal quality assurance/quality control procedures. Excellent results were obtained for calculated spiked samples.

RESULTS

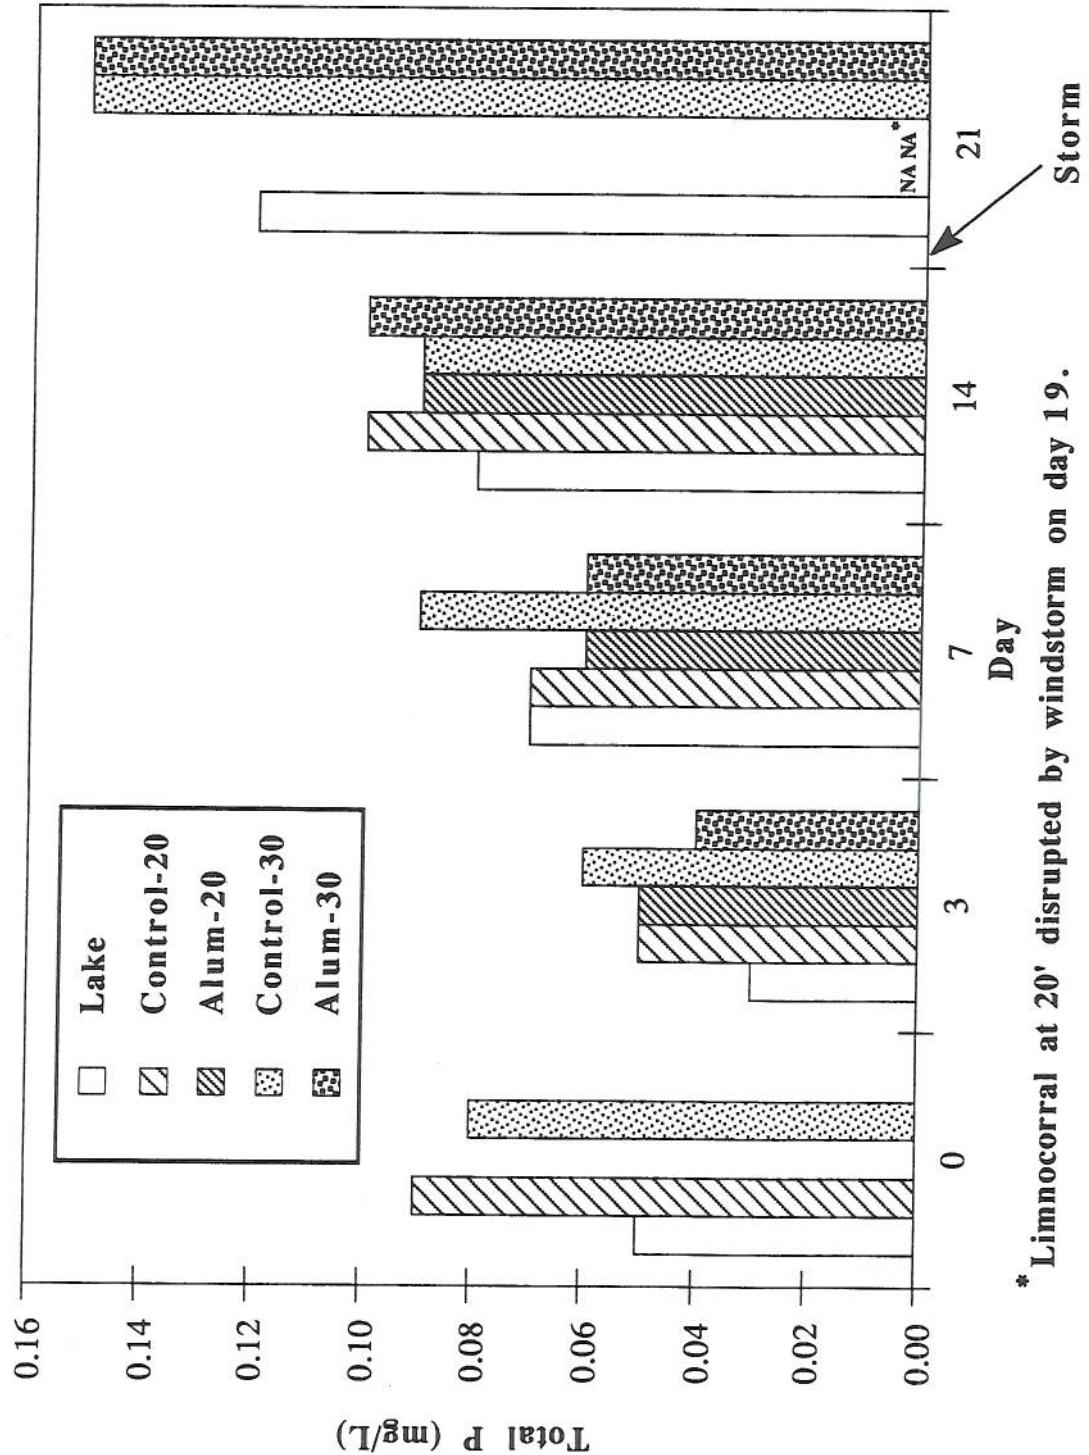

Results of water quality analysis from IML are provided in Appendix A. Results of field measurements are provided in Appendix B. Plots of the results of the total phosphorus analysis are provided in Figure 1. Plots of the results of total and dissolved reactive phosphorus analysis are provided in Figure 2.

DISCUSSION AND CONCLUSIONS

Alum/Sodium aluminate Treatment - There was very little difference between the control limnocorras and the alum test limnocorras (see Figure 1). A small decrease in total phosphorus between control and treatment was seen in the 3-day and 7-day 30 foot limnocorras, and in the 7-day and 14-day 20 foot limnocorras. However, total phosphorus was increasing over this period, including in the lake. By day 21, the 30 foot limnocorras showed no difference between control and test, and were higher than the total phosphorus in the lake. No significant phosphorus complexation and precipitation occurred versus controls past day 7.

Phosphorus Addition - The results of phosphorus addition to the limnocorras was very interesting. An amount of dissolved orthophosphorus was added that had been calculated to

raise the lake water to an estimated 600 ug/L. This was achieved in both the 30-foot limnocorras (580 ug/L total reactive phosphorus) and 20-foot limnocorras (597 ug/L total reactive phosphorus). Figure 2 illustrates what happened to the total and dissolved reactive phosphorus over the test. Total phosphorus increased in the lake, with dissolved reactive phosphorus remaining about the same. However, in both the limnocorras, total and dissolved reactive phosphorus declined in the water column. Thus, dissolved phosphorus was apparently complexed and settled out throughout the test. Recall that the 20-foot limnocorras were disrupted at Day 19, so an increase in total phosphorus was seen toward the end of the test versus the 30-foot results which indicated sustained sedimentation and removal. The total and dissolved reactive phosphorus were virtually the same as in the lake by day 21 in the 30-foot limnocorras. It is also interesting to note that the dissolved reactive phosphorus was about the same in the limnocorras receiving phosphorus addition as compared to the alum treatment at day 14 and beyond.

The concepts that 1) there is a relatively constant pool of dissolved reactive phosphorus in the lake, and 2) significant changes in total phosphorus can occur due to resuspension of bottom sediments are supported by the study. Doubling of total phosphorus concentrations is achievable, even when water is isolated in plastic enclosures. Results of this limnocorral study need to be linked to the results of the limiting nutrient study to further examine the phosphorus situation. It is doubtful that phosphorus was the limiting nutrient to algal growth during the summer growing season of 1991.

The general surface water conditions of the reservoir were acceptable this year according to numerous interviews at the reservoir of various users. Perceptions of those interviewed tended to be highly biased toward the visual characteristics of the surface. However, significant oxygen depletions were measured (Appendix B). These will be discussed in more detail in the Limiting Nutrient Study.
